2013

La presente publicación de *Valores normales de precipitación mensual 1981-2010* ha sido elaborada por el Departamento de Producción de la Agencia Estatal de Meteorología, con la colaboración de **José Antonio Guijarro** de la Delegación Territorial de AEMET en Illes Balears.

La homogeneización y el relleno de lagunas de las series han sido llevados a cabo por **José Antonio Guijarro Pastor**, Jefe de Unidad de Estudios Meteorológicos del Mediterráneo.

El tratamiento de datos y la presentación de la información han sido realizados por el técnico **Alberto Jiménez de Mingo**.

La coordinación con las unidades de Climatología de las Delegaciones Territoriales y con el Banco Nacional de Datos Climatológicos ha estado a cargo de **Celia Flores Herráez**, Jefa del Servicio del BNDC.

La coordinación técnica ha sido llevada a cabo por **Mª Roser Botey Fullat** y la supervisión por **Antonio Mestre Barceló**, del Área de Climatología y Aplicaciones Operativas.

PROLOGO

La precipitación es un elemento climático fundamental, tanto para la caracterización del clima como en relación con las tareas de vigilancia climática. Presenta una serie de particularidades debido a su gran variabilidad, tanto en su distribución espacial como en el tiempo y tiene una especial incidencia en muchos de los fenómenos que tienen lugar en el dominio de la biosfera, y por ello sobre gran parte de las actividades humanas.

Es por tanto preciso llevar a cabo una vigilancia continuada de las precipitaciones, lo que previamente requiere disponer como información de referencia, de los valores medios de la precipitación total mensual en un número suficiente de estaciones distribuidas por el territorio nacional. Para cumplir con este objetivo, la Agencia Estatal de Meteorología ha confeccionado esta publicación en la que se ponen a disposición de los diferentes usuarios de la información climática, los valores normales de precipitación para el período 1981-2010, elaborados con una metodología uniforme para un amplio conjunto de observatorios.

Antonio Mestre Barceló
Jefe del Área de Climatología y Aplicaciones Operativas

1. INTRODUCCIÓN

El estudio del comportamiento de las precipitaciones en un área y tiempo determinados precisa conocer los valores registrados de dicho parámetro a lo largo de un periodo de tiempo suficientemente largo. La Organización Meteorológica Mundial (OMM) establece este periodo de tiempo como mínimo en 30 años.

En esta publicación se pretende obtener los valores normales de precipitación total mensual, como valores medios del periodo 1981-2010, a partir de los datos registrados en el Banco Nacional de Datos Climatológicos de AEMET (BNDC). Se eligen estaciones meteorológicas que cumplan con determinadas condiciones relativas a la calidad de los datos y al número de años en los que existe el registro de precipitación.

Para solucionar el problema que se plantea sobre la homogeneidad de las series y la falta de datos en algunos periodos, se ha utilizado el paquete “Climatol”, desarrollado por José Antonio Guijarro.

El paquete “Climatol” contiene un conjunto de programas en “R” que a partir del tratamiento de los datos permite, entre otras aplicaciones, detectar las inhomogeneidades de las series, reconstruirlas y realizar el relleno de datos faltantes. Los cambios en el sistema de observación o en las condiciones del entorno donde se ubique una estación pueden producir cambios en una serie que no responden a una verdadera variabilidad climática, por lo que se ha considerado necesario seleccionar series que dentro del periodo 1981-2010 no tuvieran cambios importantes.

2. OBJETO

En este documento se exponen los procedimientos que se han llevado a cabo para obtener los valores normales de precipitación mensual para el periodo 1981-2010 en una serie de estaciones meteorológicas cubriendo todo el territorio Nacional.

El objeto de este proyecto es obtener los valores normales realizando el relleno de lagunas en varias etapas:

Primera fase:

- Seleccionar del BNDC estaciones meteorológicas con al menos 15 años de precipitación total mensual en el periodo 1981-2010.
- Realizar una primera homogeneización y relleno de lagunas para las estaciones anteriormente seleccionadas. Detectar cambios de serie y datos anómalos. (Proceso realizado mediante el paquete “Climatol”).

Segunda fase:

- Volver a determinar la selección de estaciones que se utilizan para el estudio, eliminando de las estaciones seleccionadas anteriormente las que en el periodo 1981-2010 tuvieran saltos de serie o una gran cantidad de datos de dudosa calidad. También se restringe a estaciones que al menos disponen del 60% de los datos en el periodo 1981-2010.

- De las estaciones así seleccionadas se ha realizado una nueva consulta en octubre de 2012 al BNDC para obtener los datos de precipitación total mensual y se han tratado de nuevo mediante “Climatol”, pero sólo para realizar el relleno de lagunas.
- Se han calculado los valores normales de precipitación total mensual para el periodo 1981-2010 de todas las estaciones seleccionadas en esta segunda fase después de haber realizado el relleno de lagunas.

3. PRIMERA FASE: ESTUDIO DE LAS SERIES DE PRECIPITACIÓN

3.1. Selección de estaciones con más de 15 años

Previamente a la homogeneización y al relleno de lagunas de las series de precipitación mensual, se ha realizado una consulta al BNDC para obtener los indicativos de las estaciones meteorológicas que disponen de al menos 15 años de registros en el periodo 1981-2010 y que no presentaran problemas en la observación de la precipitación. Para contar un determinado año se ha tomado el criterio de que existiera al menos un mes con registro de precipitación mensual en dicho año. De esta forma se han obtenido 4.350 estaciones meteorológicas repartidas por todo el territorio nacional.

3.2. Estudio de las series

Con cada una de las estaciones seleccionadas, se han obtenido todos los registros de precipitación mensual existentes en el BNDC, considerando los datos de precipitación total mensual sólo cuando el número de días del mes en que no hay dato de precipitación es menor o igual que dos.

Se ha procedido a la homogeneización y relleno de lagunas mediante la utilización del programa “Climatol” (versión 2.1), cuya función *homogen* comienza por calcular la raíz cúbica de todas las precipitaciones mensuales superiores a 1 mm para aproximar su distribución de frecuencias a la de una normal, y estandarizar todos los datos mensuales restándoles su valor medio y dividiéndolos por su desviación típica. Después se reconstruyen los datos de todas las series como promedios de los valores más próximos espacialmente (hasta un máximo de 10), y las diferencias entre los valores observados y los calculados sirven para formar series de anomalías, que son la base para estudiar los datos más anormales y la estabilidad de las medias a lo largo del tiempo.

Los datos cuya anomalía estandarizada supera 7 desviaciones típicas se consideran erróneos y se borran, y se ha elegido este umbral tan elevado para evitar el rechazo de datos puntuales muy elevados que se dan con cierta frecuencia en situaciones de inestabilidad, por aguaceros tormentosos que pueden ser muy abundantes pero afectar a una o muy pocas estaciones. La existencia de saltos bruscos en las medias de las anomalías se estudia mediante la prueba SNHT (Alexandersson, 1986), que se aplica primero sobre ventanas de 120 términos desplazadas hacia adelante de 60 en 60 (para evitar posibles fallos de detección en las series con saltos múltiples), y después sobre toda la serie (donde la prueba resulta más sensible). Las series con los valores SNHT más significativos se fragmentan en dos, asignando la segunda porción a una nueva

estación con las mismas coordenadas que la de la serie madre. Esto no se lleva a cabo con todos los valores de SNHT significativos, sino que se aplica únicamente a los mayores valores de esa prueba, para luego repetir todo el proceso desde el principio, hasta que ningún valor de SNHT supera un umbral prefijado (25 en la prueba sobre ventanas y 50 sobre la serie completa, más sensible, para evitar una excesiva fragmentación de las series).

La última fase del proceso de homogeneización se dedica a llenar todas las lagunas de datos, tanto las originales como las sobrevenidas por borrado de datos anómalos o por fragmentación de las series (se reconstruye una serie completa para cada uno de los fragmentos resultantes). Para el relleno de lagunas se usa el mismo método de estima de datos anterior, sólo que aquí la media de los valores estandarizados más próximos se pondera inversamente al cuadrado de la distancia, mediante el factor $1/(1+d^2/25)$, que hace que el peso de un dato situado a 5 km se reduzca a la mitad. (Este valor de ponderación se eligió porque era el que minimizaba los errores cuadráticos medios de las estimas en unas pruebas exploratorias realizadas previamente). Este proceso se ha aplicado independientemente para cada cuenca hidrográfica principal.

La aplicación se ha llevado a cabo por cuencas, y para cada una de ellas se han obtenido los gráficos de diagnóstico de cada fase del proceso y los ficheros correspondientes a los datos de las series homogeneizadas y rellenadas, incluyendo información sobre el porcentaje de datos originales, el índice de la serie madre y el valor final de la prueba SNHT.

Los valores medios para el periodo 1981-2010 se han obtenido con ayuda de otra función del paquete “Climatol” llamada *dahstat*, que genera diferentes estadísticos a partir de las series previamente homogeneizadas (Guíjarro, 2011).

3.3. Revisión de datos y selección de estaciones

Con los resultados anteriores se ha realizado una segunda revisión de las series y se ha procedido a la corrección de datos si fuera el caso, comparando con la información original de cada estación.

Se han elegido para la publicación definitiva de los valores normales de precipitación mensual 1981-2010 los datos de las estaciones meteorológicas que cumplieran con los siguientes requisitos:

- No presentar salto de serie significativo entre 1981-2010.
- Los valores que aparecieron como erróneos en la primera fase se han podido comprobar o en su caso corregir.
- Disponían de más del 60% de los datos del periodo 1981-2010, es decir, con registros en al menos 18 de los 30 años.

El número de estaciones así seleccionadas para dar información de valores normales de precipitación mensual para el periodo 1981-2010 es de 2.621 y su distribución geográfica se puede apreciar en las Figuras 1 y 2.

Fig.1. Distribución de estaciones meteorológicas en Península y Baleares

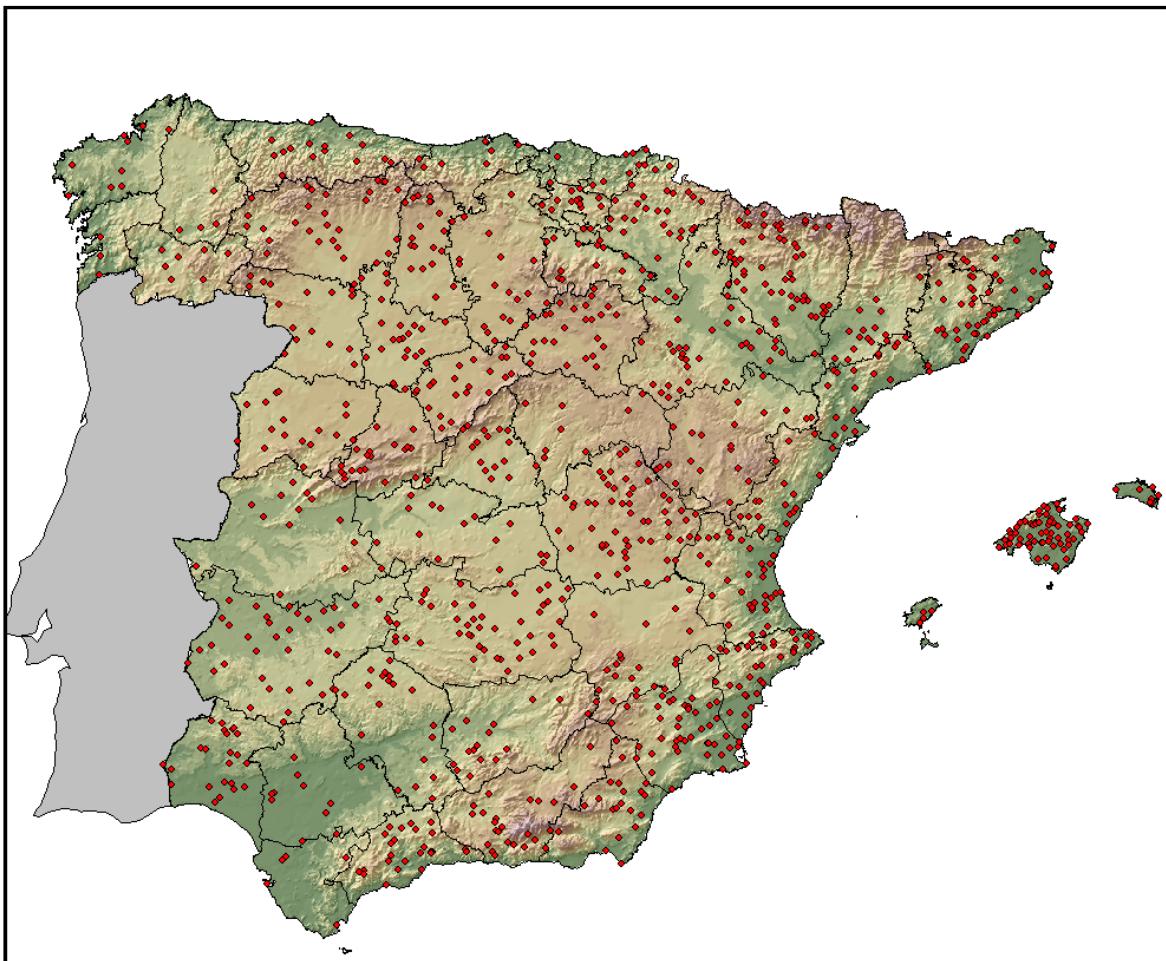

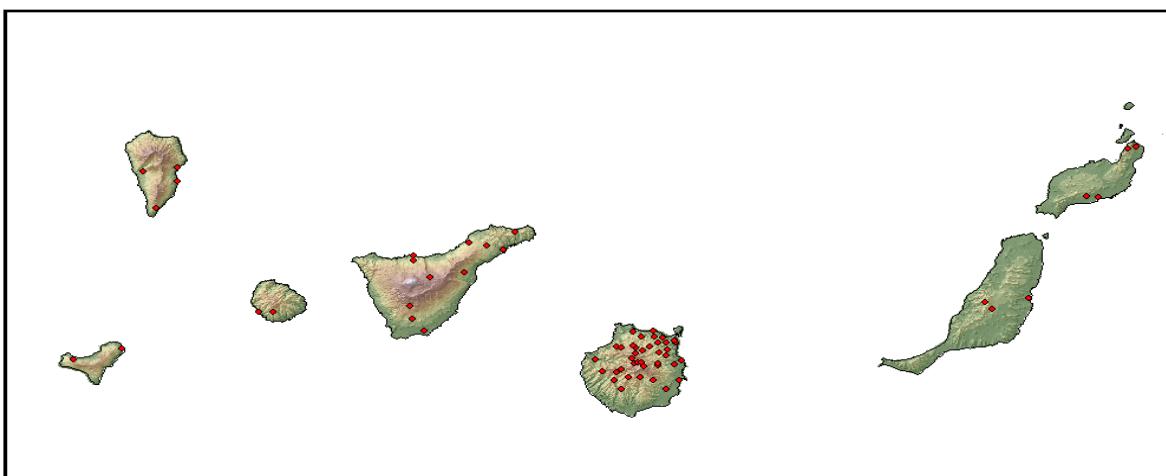

Fig.2. Distribución de estaciones meteorológicas en islas Canarias

4. SEGUNDA FASE: RELLENO DE LAGUNAS Y VALORES NORMALES

4.1.- Consultas al BNDC y relleno de lagunas

Una vez seleccionadas las estaciones meteorológicas, tal como se indica en el apartado anterior, se ha procedido a realizar las consultas definitivas al BNDC para obtener los datos de precipitación mensual, con las siguientes consideraciones:

- Los indicativos de las estaciones coinciden con las estaciones seleccionadas.
- La consulta de datos de precipitación mensual se realiza en una fecha determinada y se seleccionan sólo valores que dispongan de dato en todos los días del mes o que les falten como máximo 2 días. Se selecciona el periodo 1981-2010 y el periodo 1971-2010 para ver como influye este cambio en la utilización del programa.
- Paralelamente se realiza una “Consulta” a la base de datos para las mismas estaciones sin las restricciones anteriores de manera que al finalizar el trabajo de relleno de lagunas se puedan realizar comparaciones con el resto de datos que se encuentren en el BNDC.

Sobre los datos así obtenidos se ha procedido al relleno de lagunas con la misma metodología explicada en el apartado 3.2, aunque en este caso se han evitado los pasos de detección/corrección de saltos en la media, dado que se aplicaba sobre series seleccionadas por su mayor calidad.

4.2.- Valores normales y selección de series completas

Los valores normales de precipitación mensual para el periodo 1981-2010 se han obtenido para las 2.621 estaciones seleccionadas, calculando el valor medio mensual de los 30 meses una vez realizado el relleno de lagunas.

Para la presentación de la serie completa de valores de precipitación mensual se han elegido sólo aquellas estaciones en las que el relleno de lagunas se ha realizado en menos de 24 meses de los 360 posibles (12x30) y con la condición de que ningún dato rellenado fuera el máximo en su correspondiente serie mensual. Los datos completos de las series de precipitación mensual para los 30 años relativos a las 1.116 estaciones seleccionadas se presentan en otra publicación de AEMET denominada *Series de Precipitación mensual 1981-2010*.

5. PRESENTACIÓN DE LA INFORMACIÓN

En la presente obra *Valores Normales de precipitación mensual 1981-2010* se explica la metodología utilizada e incluye los valores normales de precipitación mensual del periodo 1981-2010 de 2.621 estaciones meteorológicas.

Para facilitar el manejo de la información elaborada para esta publicación, se presentan agrupados en una única unidad comprimida, los siguientes archivos:

Valores Normales 1981_2010.pdf: Este archivo constituye el presente documento (*Valores Normales de Precipitación Mensual 1981-2010.*) en el que se incluye también en el ANEXO1 el listado de estaciones con sus valores normales de precipitación por mes y por año. Las estaciones se ordenan separándolas por Comunidades Autónomas y provincia dentro de cada Comunidad. En la última columna se indica si dicha estación se incluye en la publicación *Series de Precipitación mensual 1981-2010*.

Valores Normales 1981_2010.xls: Este archivo constituye una herramienta fundamental para la selección de estaciones y la obtención de los valores normales. Esta implementada en “Excel” y permite utilizar filtros para seleccionar diferentes campos (Indicativo climatológico, Cuenca, Nombre de estación, Provincia, Coordenada X, Coordenada Y, y existencia de la serie completa), así como visualizar esquemáticamente su ubicación en un mapa. Las coordenadas geográficas X e Y , corresponden a una proyección UTM en el huso 30. También se pueden seleccionar estaciones por distancia a un punto conocido.

Valores_Normales 1981_2010.txt : En este archivo se proporcionan los valores normales de cada estación para cada mes incluyendo además del Indicativo de la estación, su nombre, Comunidad Autónoma y Provincia. Se trata de un fichero ASCII con separador de campo punto y coma (“;”), y separador decimal punto(“.”)
